

What's New 'Cliff Notes'

Network Edge 1.3

Network Edge is a network function virtualization infrastructure platform that is optimized for instant deployment and interconnection of network services. Users can select, configure, and connect virtual network functions, such as routers, firewall and SD-WAN capability in minutes at the edge.

New Device Vendor: Versa SD-WAN

You can select Versa SD-WAN as an available vendor and deploy a device to create a connection. As use cases are expanded for Network Edge Services, especially into SD-WAN, additional throughput will be required from your internet connection or connections to other existing Telco services.

Forced Click on Order Terms

Unlike in previous releases, you now must accept or decline the order terms. This step cannot be skipped. In addition, you can print the order terms before placing the order.

Expose Interfaces Tab

This functionality allows users with an active device on the NES to view the interfaces and its details, and allows them to control and manage the input and output of all data sources to their device. Users can also make decisions about network architecture and design from the portal or API, without the need to view raw configuration details from within the device.
